W3C Proposed Recommendation

rdf:PlainLiteral: A Datatype for RDF Plain Literals

W3C Proposed Recommendation 22 September 2009

Abstract

This document presents the specification of a primitive datatype for the plain literals of RDF.

Status of this Document

May Be Superseded

This section describes the status of this document at the time of its publication. Other documents may supersede this document. A list of current W3C publications and the latest revision of this technical report can be found in the W3C technical reports index at http://www.w3.org/TR/.

W3C Proposed Recommendation

XML Schema Datatypes Dependency

OWL 2 is defined to use datatypes defined in the XML Schema Definition Language (XSD). As of this writing, the latest W3C Recommendation for XSD is version 1.0, with version 1.1 progressing toward Recommendation. OWL 2 has been designed to take advantage of the new datatypes and clearer explanations available in XSD 1.1, but for now those advantages are being partially put on hold. Specifically, until XSD 1.1 becomes a W3C Recommendation, the elements of OWL 2 which are based on it should be considered *optional*, as detailed in Conformance, section 2.3. Upon the publication of XSD 1.1 as a W3C Recommendation, those elements cease to be optional and are to be considered required as otherwise specified.

We suggest that for now developers and users follow the XSD 1.1 Candidate Recommendation. Based on discussions between the Schema and OWL Working Groups, we do not expect any implementation changes will be necessary as XSD 1.1 advances to Recommendation.

Summary of Changes

There have been no substantive changes since the previous version. For details on the minor changes see the change log and color-coded diff.

W3C Members Please Review By 20 October 2009

The W3C Director seeks review and feedback from W3C Advisory Committee representatives, via their review form by 20 October 2009. This will allow the Director to assess consensus and determine whether to issue this document as a W3C Recommendation.

Others are encouraged by the OWL Working Group and the Rule Interchange Format (RIF) Working Group to continue to send reports of implementation experience, and other feedback, to public-owl-comments@w3.org (public archive). Reports of any success or difficulty with the test cases are encouraged. Open discussion among developers is welcome at public-owl-dev@w3.org (public archive).

Support

The advancement of this Proposed Recommendation is supported by the disposition of comments on the Candidate Recommendation, the Test Suite with Test Results, and the list of implementations.

W3C Proposed Recommendation

No Endorsement

Publication as a Proposed Recommendation does not imply endorsement by the W3C Membership. This is a draft document and may be updated, replaced or obsoleted by other documents at any time. It is inappropriate to cite this document as other than work in progress.

Patents

This document was produced by a group operating under the 5 February 2004 W3C Patent Policy. W3C maintains a public list of any patent disclosures made in connection with the deliverables of the group; that page also includes instructions for disclosing a patent. An individual who has actual knowledge of a patent which the individual believes contains Essential Claim(s) must disclose the information in accordance with section 6 of the W3C Patent Policy.

W3C Proposed Recommendation

1 Introduction

The Resource Description Framework [*RDF*] is defined to have an extensible system of typed literals, based on XML Schema datatypes [*XSD*], and also to have plain literals. In the RDF specification, plain literals differ from typed literals in that plain literals have no datatype and can optionally have a language tag, indicating the natural language of the content. (See Tags for Identifying Languages [*BCP 47*]). These options for expressing RDF literals complicate specifications which interact with RDF, such as RIF and OWL. Furthermore, RDF does not provide a name for the set of all plain literals, which, for example, prevents one from stating in RDFS or OWL that the range of some property must be a plain literal.

In response, this specification introduces a datatype called rdf:PlainLiteral. The datatype is in the "rdf:" namespace because it refers to parts of the conceptual model of RDF. This extension, however, does not change that conceptual model, and thus does not affect specifications that depend on it, such as SPARQL [*SPARQL*]. The value space of rdf:PlainLiteral consists of all data values assigned to RDF plain literals, which allows RDF applications to explicitly refer to this set (e.g., in rdfs:range assertions).

Because RDF plain literals are already a part of RDF and SPARQL syntaxes, rdf:PlainLiteral literals are written as RDF plain literals in RDF and SPARQL syntaxes.

As with plain literals, this datatype can associate language tags with Unicode strings, but it does not provide its own facilities for representing natural language utterances. Unicode bidirectional control characters [*BIDI*] may be used within these literals, like all other Unicode characters. (Richer, XML-based representations such as XHTML [*XHTML*] and Ruby annotations [*RUBY*] can be expressed using the rdf:XMLLiteral datatype.)

2 Preliminaries

A *character* is an atomic unit of text. Each character has a Universal Character Set (UCS) code point [*ISO/IEC 10646*] (or, equivalently, a Unicode code point [*UNICODE*]) that *must* match the Char production from XML [*XML*] thus ensuring compatibility with XML Schema Datatypes [*XML Schema Datatypes*]. Code points are sometimes represented in this document as U+ followed by a four-digit hexadecimal value of the code point.

A *string* is a finite sequence of zero or more characters. The *length* of a string is the number of characters in it. Strings are written in this specification by enclosing them in double quotes. Two strings are identical if and only if they contain exactly the same characters in exactly the same sequence.

> **Example:**

UCS [*ISO/IEC 10646*] and Unicode [*UNICODE*] provide for 1,114,112 different code points. The Char production from XML [*XML*], however, excludes the surrogate code points and the code points U+FFFE and U+FFFF. Thus, `rdf:PlainLiteral` provides a total of 1,112,033 different characters. This number is important, as it can affect the satisfiability of an OWL 2 ontology. Consider the following example:

```
ClassAssertion( MinCardinality( n a:property
DatatypeRestriction( xs:string xs:length 1 ) ) a:i )
```

This OWL 2 axiom states that the individual `a:i` is connected by the property `a:property` to at least *n* different strings of length one. The number of such strings is limited to 1,112,033 by the above definitions, so this ontology is satisfiable if and only if *n* is smaller than or equal to 1,112,033.

A *language tag* is a string matching the `langtag` production from BCP 47 [*BCP 47*]. Furthermore, note that this definition corresponds to the *well-formed* rather than the *valid* class of conformance in BCP 47. A language tag *may* contain subtags that are not registered in the IANA Language Subtag Registry, although an `rdf:PlainLiteral` implementation *may* also choose to reject such invalid language tags.

Example:

The language tag `"en-fubar"` is not registered with the IANA Language Subtag Registry, so an `rdf:PlainLiteral` implementation is allowed to reject it. This string, however, matches the `langtag` production from BCP 47, so it is a perfectly valid language tag for the purpose of this specification. Consequently, the value space of `rdf:PlainLiteral` (see Section 3 for its definition) contains, say, the pair < `"some string"` , `"en-fubar"` >.

This specification uses Uniform Resource Identifiers (URIs) for naming datatypes and their components, which are defined in RFC 3986 [*RFC 3986*]. For readability, URIs prefixes are often abbreviated by a short prefix name according to the convention of RDF [*RDF*]. The following prefix names are used throughout this document:

- the prefix name `xs:` stands for `http://www.w3.org/2001/XMLSchema#`
- the prefix name `rdf:` stands for `http://www.w3.org/1999/02/22-rdf-syntax-ns#`

The names of the built-in functions defined in Section 5 are QNames, as defined in the XML namespaces specification [*XML Namespaces*]. The following namespace abbreviations are used in Section 5:

- `fn` stands for the `http://www.w3.org/2005/xpath-functions` namespace
- `plfn` stands for the `http://www.w3.org/2009/rdf-PlainLiteral-functions` namespace

Whether an expression of the form `pr:ln` denotes an abbreviated URI or a QName should be clear from the context: only the names of the built-in functions in Section 5 are QNames; all other such expressions denote abbreviated URIs.

Datatypes are defined in this document along the lines of XML Schema Datatypes [*XML Schema Datatypes*]. Each datatype is identified by a URI and is described by the following components:

- The *value space* is a set determining the set of values of the datatype. Elements of the value space are called *data values*.
- The *lexical space* is a set of strings that can be used to refer to data values. Each member of the lexical space is called a *lexical form*, and it is mapped to a particular data value.
- The *facet space* is a set of facet pairs of the form `( F v )`, where `F` is a URI called a *constraining facet*, and `v` is an arbitrary data value called a *constraining value*. Each such facet pair is mapped to a subset of the value space of the datatype.

A *plain literal* is a string with an optional language tag [*RDF*]. A plain literal without a language tag is interpreted in an RDF interpretation by itself. A plain literal with a language tag can be written as `"`*abc*`"@`*langTag*, and is interpreted in an RDF interpretation as a pair `< "`*abc*`" , "`*langTag*`" >`.

A *typed literal* consists of a string and a datatype URI [*RDF*] and can be written as `"abc"^^datatypeURI`. Given an RDF datatype identified by `datatypeURI`, an RDF datatyped-interpretation that includes the datatype interprets the typed literal as the data value that the datatype assigns to the lexical form `"abc"`.

The italicized keywords *must*, *must not*, *should*, *should not*, and *may* specify certain aspects of the normative behavior of tools implementing this specification, and are interpreted as specified in RFC 2119 [*RFC 2119*].

3 Definition of the `rdf:PlainLiteral` Datatype

The datatype identified by the URI `http://www.w3.org/1999/02/22-rdf-syntax-ns#PlainLiteral` (abbreviated `rdf:PlainLiteral`) is defined as follows.

W3C Proposed Recommendation

Value Space. The value space of `rdf:PlainLiteral` consists of

- all strings, and
- all pairs of the form < "*abc*" , "*lc-langtag*" > where "*abc*" is a string and "*lc-langtag*" is a lowercase language tag.

Lexical Space. An `rdf:PlainLiteral` lexical form is a string of the form "*abc@langTag*" where "*abc*" is an arbitrary (possibly empty) string, and "*langTag*" is either the empty string or a (not necessarily lowercase) language tag. Each such lexical form is mapped to a data value `dv` as follows:

- If "*langTag*" is empty, then `dv` is equal to the string "*abc*" and
- If "*langTag*" is not empty, then `dv` is equal to the pair < "*abc*", "*lc-langtag*" > where "*lc-langtag*" is "*langTag*" normalized to lowercase.

Example:

The following table shows several `rdf:PlainLiteral` lexical forms and their corresponding data values.

Lexical form	Corresponding data value
`"Family Guy@en"`	`< "Family Guy" , "en" >`
`"Family Guy@EN"`	`< "Family Guy" , "en" >`
`"Family Guy@FOX@en"`	`< "Family Guy@FOX" , "en" >`
`"Family Guy@"`	`"Family Guy"`
`"Family Guy@FOX@"`	`"Family Guy@FOX"`

The following table shows several of strings that are not `rdf:PlainLiteral` lexical forms.

String	The reason for not being an **rdf:PlainLiteral** lexical form
`"Family Guy"`	does not contain at least one `@` (U+0040) character
`"Family Guy@12"`	`"12"` is not a language tag according to BCP 47

Facet Space. The facet space of `rdf:PlainLiteral` is defined as shown in Table 1.

Table 1. The Facet Space of `rdf:PlainLiteral`

A facet pair (`F v`) is in the facet space of `rdf:PlainLiteral` if...	Each such facet pair is mapped to the subset of the value space of `rdf:PlainLiteral` containing...
...F is `xs:length`, `xs:minLength`, `xs:maxLength`, `xs:pattern`, `xs:enumeration`, or `xs:assertion` and (`F v`) is in the facet space of `xs:string`.	...all strings of the form "*abc*" and all pairs of the form < "*abc*" , "*lc-langtag*" > such that "*abc*" is contained in the subset of the value space of `xs:string` determined by (`F v`) as specified by XML Schema Datatypes [*XML Schema Datatypes*].
...F is `rdf:langRange` and `v` is an *extended language range* as specified in Section 2.2 of [*RFC4647*].	...all pairs of the form < "*abc*" , "*lc-langtag*" > such that "*lc-langtag*" matches v under *extended filtering* as specified in Section 3.3.2 of [*RFC4647*].

Example:

The facet `xs:length` can be used to refer to a subset of strings of a particular length regardless of whether they have a language tag or not. Thus, the subset of the value space of `rdf:PlainLiteral` corresponding to the facet pair (`xs:length 3`) contains the string "abc", as well as the pairs < "abc" , "en" > and < "abc" , "de" >.

Example:

The facet `rdf:langRange` can be used to refer to a subset of strings containing the language tag. Note that the language range need not be in lowercase, and that the matching algorithm is case-insensitive. Thus, the subset of the value space of `rdf:PlainLiteral` corresponding to the facet pair (

rdf:langRange "de-DE") contains the pairs < "abc" , "de-de" > and < "abc" , "de-de-1996" > (because these match the language range "de-DE" according to RFC 4647), but not the string "abc" (because it is not a pair with a language tag) or the pairs < "abc" , "de-deva" > and < "abc" , "de-latn-de" > (because these do not match the language range "de-DE" according to RFC 4647).

Example:

The facet pair (rdf:langRange "*") is mapped to the subset of the value space of rdf:PlainLiteral containing all pairs of the form < "*abc*" , "*lc-langtag*" >. In languages such as OWL 2, this can be used to specify that a data value must contain the language tag.

4 Syntax for rdf:PlainLiteral Literals

It follows from the above that in datatyped interpretations that include the rdf:PlainLiteral datatype, the value space of rdf:PlainLiteral contains exactly all data values assigned to plain literals (with or without a language tag). The rdf:PlainLiteral datatype thus provides an explicit way of referring to this set.

To eliminate another source of syntactic redundancy and to retain a large degree of interoperability with applications that do not understand the rdf:PlainLiteral datatype, the form of rdf:PlainLiteral literals in syntaxes for RDF graphs and for SPARQL is the already existing syntax for the corresponding plain literal, not the syntax for a typed literal. Therefore, typed literals with rdf:PlainLiteral as the datatype are considered by this specification to be not valid in syntaxes for RDF graphs or SPARQL.

To implement this design and provide this interoperability, applications that employ this datatype *must* use plain literals (instead of rdf:PlainLiteral typed literals) whenever a syntax for plain literals is provided, such as in existing syntaxes for RDF graphs and SPARQL results.

Additionally, systems may need similar restrictions for non-syntactic public interfaces. For instance, in extended SPARQL basic graph matching, the results of matching SPARQL basic graph patterns in an entailment regime that understands rdf:PlainLiteral *must* provide variable bindings in existing RDF plain literal form.

5 Functions on rdf:PlainLiteral Data Values

This section defines functions that construct and operate on rdf:PlainLiteral data values. The terminology used and the way in which these functions are

described are in accordance with the XQuery 1.0 and XPath 2.0 Functions and Operators [*XPathFunc*]. Each function is identified by a QName [*XML Namespaces*]. The error codes used in this section are given in Appendix G of the XPath 2.0 specification [*XPath20*] and Appendix C of XQuery and XPath function specification [*XPathFunc*].

5.1 Functions for Assembling and Disassembling `rdf:PlainLiteral` Data Values

5.1.1 `plfn:PlainLiteral-from-string-lang`

```
plfn:PlainLiteral-from-string-lang( $arg1 as xs:string, $arg2 as xs:strin
```

Summary: returns the data value < `$arg1, lowercase($arg2)` > if `$arg2` is present, and returns the data value `$arg1` otherwise. Both arguments must be of type `xs:string` or one of its subtypes, and `$arg2` — if present — must be a (nonempty) language tag; otherwise, this function raises type error err:FORG0006. Note that, since in the value space of `rdf:PlainLiteral` language are in lowercase, this function converts `$arg2` to lowercase.

5.1.2 `plfn:string-from-PlainLiteral`

```
plfn:string-from-PlainLiteral( $arg as rdf:PlainLiteral) as xs:string
```

Summary: returns the string part `s` if `$arg` is a `rdf:PlainLiteral` data value of the form < `s, l` > or of the form `s`. If `$arg` is not of type `rdf:PlainLiteral`, this function raises type error err:FORG0006.

5.1.3 `plfn:lang-from-PlainLiteral`

```
plfn:lang-from-PlainLiteral( $arg as rdf:PlainLiteral ) as xs:language
```

Summary: returns the language tag `l` if `$arg` is an `rdf:PlainLiteral` data value of the form < `s, l` >, and returns the empty string if `$arg` is an `rdf:PlainLiteral` data value of the form `s`. If `$arg` is not of type `rdf:PlainLiteral`, this function raises type error err:FORG0006.

5.2 The Comparison of `rdf:PlainLiteral` Data Values

The notion of collations used in this section is taken from [Section 7.3.1](#) of XPath and XQuery function specification [*XPathFunc*].

5.2.1 `plfn:compare`

```
plfn:compare( $comparand1  as rdf:PlainLiteral?, $comparand2 as rdf:Plai
```

```
plfn:compare( $comparand1  as rdf:PlainLiteral?, $comparand2 as rdf:Plai
```

Summary: if either `$comparand1` or `$comparand2` is not of type `rdf:PlainLiteral`, of if `$collation` is specified but is not of type `xs:string`, this function raises type error [err:FORG0006](#). Otherwise, the function returns the empty sequence if one of the arguments is empty, if one of `$comparand1` and `$comparand2` has a language tag and the other one does not, or if the language parts of `$comparand1` and `$comparand2` are unequal; otherwise, this function returns -1, 0, or 1 depending on whether the value of the string-part of `$comparand1` (or `$comparand1` itself, respectively, if it has no language tag) is respectively less than, equal to, or greater than the value of the string-part of `$comparand2` (or `$comparand2` itself, respectively, if it has no language tag). The collation used by the invocation of this function is determined according to the rules in Section 7.3.1 of the XPath and XQuery functions specification [*XPathFunc*].

The first version of this function backs up the XQuery operators `"eq"`, `"ne"`, `"gt"`, `"lt"`, `"le"`, and `"ge"` on `rdf:PlainLiteral` values.

The two functions may be viewed as declared XQuery functions with the following definitions:

```
declare function  plfn:compare( $comparand1 as rdf:PlainLiteral?, $compar
  {
   return
     if ( fn:empty($comparand1) ) then $comparand1
     else if ( fn:empty($comparand2) ) then $comparand2
     else if ( fn:compare (  plfn:lang-from-PlainLiteral( $comparand1 ), p
        fn:compare (  plfn:string-from-PlainLiteral( $comparand1 ), plfn:s
  }
```

```
declare function  plfn:compare( $comparand1  as rdf:PlainLiteral?, $compa
  {
```

```
   return
    if ( fn:empty($comparand1) ) then $comparand1
    else if ( fn:empty($comparand2) ) then $comparand2
    else if ( fn:compare ( plfn:lang-from-PlainLiteral( $comparand1 ),   p
         fn:compare (  plfn:string-from-PlainLiteral( $comparand1 ) ,  plfn
  }
```

5.3 Other Functions on `rdf:PlainLiteral` Data Values

5.3.1 `plfn:length`

```
   plfn:length($arg as rdf:PlainLiteral) as xs:integer
```

Summary: returns the number of characters in the string part `s` if `$arg` is an
`rdf:PlainLiteral` data value of the form < `s`, `l` > or a string value `s`,
respectively. If `$arg` is not of type `rdf:PlainLiteral`, this function raises type
error err:FORG0006.

This function may be viewed as a declared XQuery function with the following
definition:

```
declare function  plfn:length($arg as rdf:PlainLiteral?) as xs:integer
  {
   return
      fn:string-length (  plfn:string-from-PlainLiteral( $arg ) )
  }
```

5.3.2 `plfn:matches-language-range`

```
   plfn:matches-language-range($arg as rdf:PlainLiteral?, $range as xs:stri
```

Summary: This function is only defined if `$arg` is a sequence of length 0 or 1 of
literals of type `rdf:PlainLiteral` and `$range` is of type `xs:string`; if the
parameters do not satisfy these typing conditions, the function raises a type error
err:FORG0006. If the typing conditions are fulfilled, the function returns `true` in
case `$arg` is an `rdf:PlainLiteral` data value of the form < `s`, `l` > with `l` a
language tag that matches the extended language range `$range` as specified by
the extended filtering algorithm for "Matching of Language Tags" [*BCP-47*];
otherwise, it returns `false`. This means that the function returns `false` if the
argument is a string `rdf:PlainLiteral` data value. An empty input sequence is

W3C Proposed Recommendation

treated as a `rdf:PlainLiteral` data value consisting of the empty string, and accordingly on such input this function also returns `false`.

6 Acknowledgments

The RIF and OWL Working Groups made parallel efforts to support strings with associated language tags, as found in RDF. This specification is the outcome of a collaboration between the two groups, and it is based on the work on the datatypes `rif:text` and `owl:internationalizedString`.

In addition to members and chairs of both Working Groups, the editors would like to thank Addison Phillips, C. Michael Sperberg-McQueen, Eric Prud'hommeaux, Andy Seaborne, and Pat Hayes, along with other participants of the public-rdf-text mailing list, for their assistance in working out the details of this specification.

8 Appendix: Change Log (Informative)

8.1 Changes Since Candidate Recommendation

This section summarizes the changes to this document since the Candidate Recommendation of 11 June, 2009.

- The "At Risk" warnings were removed. The indicated features remain in the document.
- An error in the order of parameters in an example was corrected
- xs:assertions and xs:lang were corrected to xs:assertion and xs:language
- The references to XML Schema Datatypes were rephrased to account for version 1.1 not yet being a Recommendation

8.2 Changes Since Last Call

Since the last call draft of 21 April 2009, the following changes have been made:

- The name of the datatype was changed from rdf:text to rdf:PlainLiteral, to clarify the role and purpose of the datatype
- The names of the builtins and their namespace were changed to match the change in the name of the datatype
- The introduction and section 4 were rewritten to reframe this datatype as having a special relationship to RDF plain literals.
- The notion of an entailment relationship between plain literals and rdf:PlainLiteral typed literals was removed, since rdf:PlainLiterals are now more clearly understood to not occur in RDF graph syntaxes.
- The characters used to delimit pairs was changed, since problems were reported with ⟨ and ⟩ in some browsers
